

NORM MINIMA IN CERTAIN SIEGEL LEAVES

LI CAI

ABSTRACT. In this paper we shall illustrate that each polytopal moment-angle complex can be understood as the intersection of the minima of corresponding Siegel leaves and the unit sphere, with respect to the maximum norm. Consequently, an alternative proof of a rigidity theorem of Bosio and Meersseman is obtained; as piecewise linear manifolds, polytopal real moment-angle complexes can be smoothed in a natural way.

1. INTRODUCTION

An *admissible configuration* of m complex vectors in $\mathbb{C}^{d/2}$ ($m > d$ with d even) satisfying so called *Siegel* and *weak hyperbolicity* conditions (cf. [Mee00, p. 82]; see Section 2 for a real analogue), gives rise to a free action on \mathbb{C}^m via exponential functions. There are two types of leaves in the holomorphic foliation given by this action: a leaf is of *Siegel type* if the origin is not in its closure, otherwise it is said of Poincaré type.

These objects originated in the work [CKP78] of C. Camacho, N. Kuiper and J. Palls on the complex analogue of a dynamical system for which the real version appeared in an earlier work of Poincaré, and later have been developed and generalized by S. López de Medrano, A. Verjovsky and L. Meersseman (cf. [LV97], [Mee00]). From their works, the projectivization of the minima of all Siegel leaves, with respect to the Euclidean norm, can be endowed with the structure of a compact, complex $(m - d/2 - 1)$ -manifold C^∞ -embedded in $\mathbb{C}P^{m-1}$, which is not symplectic except the trivial case. This class of complex manifolds is now named as *LVM manifolds*.

On the other hand, with a direct calculation, the space of minima of all Siegel leaves can be described by d *real quadratics* arising from the given configuration in \mathbb{R}^d , whose intersection with unit Euclidean sphere in \mathbb{C}^m is transverse hence is a smooth manifold of real dimension $2m - d - 1$. F. Bosio and L. Meersseman observed that this method also works for odd d , and call these manifolds embedded in spheres as *links* in [BM06].

2010 *Mathematics Subject Classification*. Primary 57R30; Secondary 57R70, 05E45.

Key words and phrases. foliation, moment-angle manifold, simplicial complex.

This special class of links is a model for *polytopal moment-angle manifolds*. In general their topology is known to be complicated (cf. [BM06], [GL13]), for instance, arbitrary *torsion* can appear in the cohomology, as well as non-vanishing triple *Massey products* (cf. [Bas03], [DS07]); in the case $d = 2$, the classification work [LdM89] by S. López de Medrano shows that they are diffeomorphic to a triple product of spheres or to the connected sum of sphere products. An important way to understand them is that they inherit the natural $(S^1)^m$ -action on \mathbb{C}^m , with each quotient space homeomorphic (as manifolds with corners) to a simple convex polytope. Via the *basic construction* originating from *reflection group theory* and then generalized by M. W. Davis and T. Januszkiewicz in their influential work [DJ91], each link discussed above is homeomorphic to a *moment-angle complex* (named in [BP02]), i.e. a *polyhedral product* with pairs (D^2, S^1) corresponding to the boundary complex of a simplicial polytope.

The polyhedral product model has been studied in detail and generalized by V. Buchstaber and T. Panov in [BP02]. Later a more categorical treatment by A. Bahri, M. Bendersky, F. R. Cohen and S. Gitler in their work [BBCG10] provides a penetrating viewpoint from homotopy theory.

These spaces have spawned a large body of the work notably with Davis-Januszkiewicz [DJ91] on quasi-toric varieties, Buchstaber-Panov [BP02] on moment-angle complexes, Goresky-MacPherson [GM88] on complements of complex arrangements, S. López de Medrano [LdM89] on the topology of these varieties, as well as many others. The interconnections between these subjects is developed in the beautiful book [BP14] by Buchstaber-Panov.

The objective of this paper is to show that, for an admissible configuration of m real vectors in \mathbb{R}^d whose centroid is located at the origin, the corresponding foliation provides a direct relation between the model of links and the model of polyhedral products: there are continuous paths in the space of the union all Siegel leaves (which is the *complement of a coordinate subspace arrangement* in \mathbb{C}^m), such that each point of the link is connected by a path to a unique point in the respective moment-angle complex, yielding a homeomorphism between them. Every path is parameterized by real numbers $p \in [1, \infty)$, with each p associated to the intersection of the L^p -norm minima in the Siegel leaves and the L^p -norm unit sphere in \mathbb{C}^m , which is a topological manifold homeomorphic to the link. In this way, we can understand each polytopal moment-angle complex as the intersection of the unit sphere and the minima of all Siegel leaves, with respect to the L^∞ -norm.

This paper develops a more analytic approach to these spaces in the spirit of the work [BM06] by Bosio and Meersseman.

I would like to thank my Ph.D. supervisor, Professor Osamu Saeki for discussions.

2. NOTATIONS AND MAIN RESULTS

Let $A = (A_1, A_2, \dots, A_m)$ be an m -tuple of vectors in \mathbb{R}^d , with $m > d \geq 0$ ($A_i \equiv 0$ when $d = 0$); occasionally we treat such a tuple as a $(d \times m)$ -matrix. Denote by $[m]$ the set $\{1, 2, \dots, m\}$, and for $I \subset [m]$, let $A(I)$ be the subtuple $(A_i)_{i \in I}$ and $\text{conv} A$ (resp. $\text{conv} A(I)$) the convex hull of vectors from A (resp. from $A(I)$).

We say that A is *admissible*, if it satisfies the following two conditions (cf. [BM06, Lemma 0.3]):

- *₁ (Siegel condition) $\mathbf{0} \in \text{conv} A$;
- *₂ (weak hyperbolicity condition) if $\mathbf{0} \in \text{conv} A(I)$, then we have $\text{card}(I) > d$ (where card refers to the cardinality).

Up to Section 5, we always assume that A is admissible.

Let $\mathbb{R}_{>0}$ be the set of positive real numbers, in which $p \geq 1$ is a real number. For each $z = (z_i)_{i=1}^m \in \mathbb{C}^m$, denote by $\|z\|_p$ its L^p -norm, namely $\|z\|_p = (\sum_{i=1}^m |z_i|^p)^{\frac{1}{p}}$ where $|z_i| = \sqrt{z_i \bar{z}_i}$.

With respect to an m -tuple A , there is a smooth *foliation* \mathcal{F} of \mathbb{C}^m given by the orbits of the action

$$(1) \quad \begin{aligned} F: \mathbb{C}^m \times \mathbb{R}^d &\longrightarrow \mathbb{C}^m \\ (z, T) &\longmapsto (z_i e^{\langle A_i, T \rangle})_{i=1}^m. \end{aligned}$$

For each $z \in \mathbb{C}^m$, let L_z be the *leaf* passing through z . L_z is called a *Siegel leaf* if $\mathbf{0}$ is not in its closure, otherwise we say the leaf L_z is of Poincaré type. It follows that the union of all Siegel leaves can be described by the set (cf. [CKP78], [MV04], [BM06])

$$(2) \quad \mathcal{S}_A = \{z \in \mathbb{C}^m \mid \mathbf{0} \in \text{conv} A(I_z)\},$$

where I_z is the set of non-zero entries for $z = (z_i)_{i=1}^m$, i.e. $I_z = \{i \in [m] \mid |z_i| \neq 0\}$. With an argument involving foliations, complex analysis and the convexity, the following fact is a combination of the works mentioned above, which is our starting point:

Theorem 1 (cf. [BM06, Lemma 0.8, pp. 61–62]). *For each $z \in \mathcal{S}_A$, there is a unique point $f_2(z)$ in the leaf L_z , such that its L^2 -norm $\|f_2(z)\|_2$ is minimal and positive. The foliation \mathcal{F} is trivial when restricted to \mathcal{S}_A , and*

$$\begin{aligned} \Phi_A(2): X_A(2) \times \mathbb{R}^d \times \mathbb{R}_{>0} &\longrightarrow \mathcal{S}_A \\ (z, T, r) &\longmapsto r(z_i e^{\langle A_i, T \rangle})_{i=1}^m \end{aligned}$$

is a global diffeomorphism, where $X_A(2)$ is given by the transverse intersection

$$(3) \quad \begin{cases} \sum_{i=1}^m A_i |z_i|^2 = \mathbf{0}, \\ \|z\|_2 = 1, \end{cases}$$

thus is a smooth manifold.

It follows that there is a smooth function

$$(4) \quad T_2: \mathcal{S}_A \rightarrow \mathbb{R}^d, \text{ s.t. } f_2(z) = F(z, T_2(z)),$$

and after differentiating $F(z, T)$ with respect to $T \in \mathbb{R}^d$, one easily checks that the critical point corresponding to the minimum satisfies

$$(5) \quad \sum_{i=1}^m A_i |z_i|^2 e^{2\langle A_i, T \rangle} = \mathbf{0},$$

in which $T_2(z)$ is the unique solution. Moreover, $f_2/\|f_2\|_2: \mathcal{S}_A \rightarrow X_A(2)$ is a smooth retraction.

Following their approach, we consider the space of L^p -norm minima of those Siegel leaves. Our first main theorem is the following, whose proof is based on some real analysis and will be given in Section 3.

Theorem 2. *Let $X_A(p)$ be the intersection*

$$(6) \quad \begin{cases} \sum_{i=1}^m A_i |z_i|^p = \mathbf{0}, \\ \|z\|_p = 1. \end{cases}$$

There is a unique point $f_p(z)$ in the leaf L_z for each $z \in \mathcal{S}_A$, whose L^p -norm $\|f_p(z)\|_p$ is minimal and positive, and the restriction of the smooth function $f_2/\|f_2\|_2: \mathcal{S}_A \rightarrow X_A(2)$ to $X_A(p)$ induces a homeomorphism onto $X_A(2)$, for all $p \geq 1$. Moreover,

$$\begin{aligned} \Phi_A(p): X_A(p) \times \mathbb{R}^d \times \mathbb{R}_{>0} &\longrightarrow \mathcal{S}_A \\ (z, T, r) &\longmapsto r(z_i e^{\langle A_i, T \rangle})_{i=1}^m, \end{aligned}$$

is a homeomorphism.

Similar to (4), for each p we can define a continuous function $T_p: \mathcal{S}_A \rightarrow \mathbb{R}^d$ such that $f_p/\|f_p\|_p: \mathcal{S}_A \rightarrow X_A(p)$ is a retraction, where $f_p(z) = F(z, T_p(z))$ is the function of L^p -norm minima in the leaf L_z .

It is interesting to imagine what will happen when p tends to infinity, and this will be discussed in Section 4. First note that the set

$$(7) \quad K_A = \{\sigma \subset [m] \mid \mathbf{0} \in \text{conv} A([m] \setminus \sigma)\}$$

is an *abstract simplicial complex* (cf. [BM06, Lemma 0.12]), i.e. all subsets of σ will be in K_A if σ is. It turns out that with each $z \in \mathcal{S}_A$ fixed, $T_p(z)$ and

$f_p(z)/\|f_p(z)\|_p$ are continuous in $p \in [1, \infty)$ (see Proposition 4.2); when p goes to infinity, $f_p(z)/\|f_p(z)\|_p$ approaches to the *moment-angle complex* $(D^2, S^1)^{K_A}$ (see (14) and Proposition 4.4 for details), which is a subset of the intersection of \mathcal{S}_A with the L^∞ -norm unit sphere in \mathbb{C}^m ($\|z\|_\infty = \max\{|z_i|\}_{i=1}^m$).

We say that the tuple A is *centered at the origin*, if the centroid of all vectors in A is located at the origin:

$$(8) \quad \sum_{i=1}^m A_i = \mathbf{0}.$$

Under this additional assumption, K_A is isomorphic to the boundary of a convex polytope arising from the *Gale transform* of A (see Proposition 5.3); based on a result of Panov and Ustinovsky in [PU12], in Section 5 we will show that $f_p(z)/\|f_p(z)\|_p$ converges to a unique point in $(D^2, S^1)^{K_A}$ as p tends to infinity. With a similar treatment as the one for Theorem 2, the following theorem holds:

Theorem 3. *Assume that A is an admissible tuple centered at the origin. Then the restriction $f_2/\|f_2\|_2|_{(D^2, S^1)^{K_A}} : (D^2, S^1)^{K_A} \rightarrow X_A(2)$ is a homeomorphism. Moreover,*

$$\begin{aligned} \Phi_A(\infty) : (D^2, S^1)^{K_A} \times \mathbb{R}^d \times \mathbb{R}_{>0} &\longrightarrow \mathcal{S}_A \\ (z, T, r) &\longmapsto r(z_i e^{\langle A_i, T \rangle})_{i=1}^m \end{aligned}$$

is a homeomorphism.

Therefore, we can understand such a moment-angle complex $(D^2, S^1)^{K_A}$ as “ $X_A(\infty)$ ”, namely the intersection of the L^∞ -norm minima in the Siegel leaves with the L^∞ -norm unit sphere in \mathbb{C}^m (the reader is encouraged to imagine the deformation from $X_A(1)$ to $X_A(\infty)$ in the case $d = 0$).

As an application, in Section 6 we give an alternative proof for a rigidity theorem of Bosio and Meersseman (cf. [BM06, Theorem 4.1]): if two admissible m -tuples A and A' are both centered at the origin such that K_A and $K_{A'}$ are isomorphic simplicially, then there is a diffeomorphism between associated links $X_A(2)$ and $X_{A'}(2)$ (see Proposition 6.1 for more details).

From its definition (1), notice that each leaf L_z is contained in $\mathcal{S}_A \cap \mathbb{R}^m$ if and only if $z \in \mathcal{S}_A \cap \mathbb{R}^m$. Hence the theorems and properties above are also true when restricted to the subspace \mathbb{R}^m in \mathbb{C}^m .

At last in Section 6, we shall illustrate that the restriction of $f_2/\|f_2\|_2$ to the real moment-angle complex $(D^1, S^0)^{K_A} = (D^2, S^1)^{K_A} \cap \mathbb{R}^m$ is a *piecewise differentiable* homeomorphism onto $X_A(2) \cap \mathbb{R}^m$, provided that A is admissible and centered at the origin (see Definition 6.2, Lemma 6.3 and Proposition 6.4 for more details). In this way these real moment-angle complexes can be smoothed, as piecewise linear manifolds.

3. PROOF OF THEOREM 2

We start with a well-known lemma due to Meersseman and Verjovsky, whose proof is omitted here:

Lemma 3.1 (cf. [MV04, Lemma 1.1], [BM06, Lemma 0.3]). *For an admissible tuple $A = (A_i)_{i=1}^m$, let $\tilde{A} = (\tilde{A}_i)_{i=1}^m$ be the augmentation with $\tilde{A}_i = (A_i^T, 1)^T \in \mathbb{R}^{d+1}$, $i = 1, 2, \dots, m$. Then for any $I \subset [m]$ such that $\mathbf{0} \in \text{conv} A(I)$, the rank of the subtuple $\tilde{A}(I)$ is $d + 1$.*

Proposition 3.2. *For each $z \in \mathcal{S}_A$ given, there is a unique point $f_p(z)$ in the leaf L_z , such that $\|f_p(z)\|_p$ is minimal and positive.*

Proof. (Uniqueness (cf. [CKP78], [Mee00], [MV04]).) Assume that F_z has two local minima, i.e. T_1 and T_2 in \mathbb{R}^d such that they are both critical points of $(\|F(z, T)\|_p)^p = \sum_{i=1}^m |z_i|^p e^{p\langle A_i, T \rangle}$, which means

$$\sum_{i=1}^m A_i |z_i|^p e^{p\langle A_i, T_j \rangle} = \mathbf{0}, \quad j = 1, 2.$$

We define a function $h: [0, 1] \rightarrow \mathbb{R}$ such that $h(t) = (\|F(z, (1-t)T_1 + tT_2)\|_p)^p$, clearly

$$(9) \quad \frac{dh}{dt} = p \sum_{i=1}^m \langle A_i, T_2 - T_1 \rangle |z_i|^p e^{p\langle A_i, (1-t)T_1 + tT_2 \rangle}.$$

From Lemma 3.1, the subtuple $A(I_z)$ has rank d ($I_z \subset [m]$ consists of entries i such that $z_i \neq 0$), which is independent of $z \in \mathcal{S}_A$, thus there exists $i \in I_z$ such that $\langle A_i, T_2 - T_1 \rangle$ does not vanish; it follows that the second derivative of h is strictly positive, hence its first derivative (9) is strictly increasing, which is a contradiction.

(Existence.) First from Cauchy-Schwarz inequality

$$(10) \quad \|F(z, T)\|_2 \leq \|F(z, T)\|_1 \leq \sqrt{m} \|F(z, T)\|_2,$$

together with Theorem 1 and the Lemma 3.3 below, we conclude that $\|F(z, T)\|_1$ bounds away from zero, and stays large whenever $\|T\|_2$ is large. Thus the minimum of $\|F(z, T)\|_1$ is positive, and it appears only when T is in the interior of a ball of finite radius. So the case $p = 1$ is clear. For general cases when $p \neq 1, 2$, Hölder's inequality implies

$$(11) \quad \|F(z, T)\|_p \leq \|F(z, T)\|_1 \leq \sqrt[p]{m} \|F(z, T)\|_p,$$

here $q > 1$ such that $1/p + 1/q = 1$. We can repeat the previous argument and then the proof is completed. \square

Lemma 3.3. *With $z \in \mathcal{S}_A$ given, for any $N > 0$, there exists $R > 0$, such that $\|F(z, T)\|_2 > N$ whenever $\|T\|_2 > R$.*

Proof. Let $T_2(z)$ be the point in \mathbb{R}^d such that $\|F(z, T_2(z))\|_2$ is minimal (see (4) for details). Denote by $u(t; T_1, T_2)$ the derivative of $(\|F(z, (1-t)T_1 + tT_2)\|_2)^2$ with respect to $t \in [0, 1]$, for $T_1, T_2 \in \mathbb{R}^d$, and let $B(r, T_2(z))$ be the ball with radius r centered at $T_2(z)$. Since $T_2(z)$ is the unique minimum, for all $y \in \partial B(1, T_2(z))$ on the boundary, there is a positive ε , such that

$$(\|F(z, y)\|_2)^2 - (\|F(z, T_2(z))\|_2)^2 = \int_0^1 u(t; T_2(z), y) dt > \varepsilon,$$

therefore we can choose $t(y) \in (0, 1)$ such that

$$u(t(y); T_2(z), y) > \varepsilon,$$

by the mean value theorem. For $r > 1$, assume that $y_r \in \partial B(r, T_2(z))$ with $y \in \partial B(1, T_2(z))$ on the ray from $T_2(z)$ to y_r , by the monotonicity of $u(t; T_2, y_r)$ (see the uniqueness part in the proof of Proposition 3.2), we have

$$u(t; y, y_r) > u(t(y); T_2, y),$$

thus

$$(\|F(z, y_r)\|_2)^2 - (\|F(z, T_2(z))\|_2)^2 = \int_0^1 u(t; T_2, y) dt + \int_0^1 u(t; y, y_r) dt > \varepsilon + (r-1)\varepsilon,$$

from which the conclusion follows. \square

The function of minima $f_p: \mathcal{S}_A \rightarrow \mathcal{S}_A$ is well defined by Proposition 3.2; but except for the case $p = 2$, it remains to prove its continuity. In what follows we shall illustrate this by showing the continuity of the restriction $f_p/\|f_p\|_p|_{X_A(2)}$ first, and then it will follow from the global diffeomorphism $\Phi_A(2)$ defined in Theorem 1.

Proposition 3.4. *The restriction $f_2/\|f_2\|_2|_{X_A(p)}$ of the smooth function $f_2/\|f_2\|_2: \mathcal{S}_A \rightarrow X_A(2)$ induces a homeomorphism onto $X_A(2)$, whose inverse is $f_p/\|f_p\|_p|_{X_A(2)}: X_A(2) \rightarrow X_A(p)$.*

Proof. Consider the function

$$\begin{aligned} \Phi_A: \mathcal{S}_A \times \mathbb{R}^d \times \mathbb{R}_{>0} &\longrightarrow \mathcal{S}_A \\ (z, T, r) &\longmapsto r(z_i e^{\langle A_i, T \rangle})_{i=1}^m, \end{aligned}$$

from Theorem 1 and Proposition 3.2, with given $z \in \mathcal{S}_A$, its image under Φ_A intersects both $X_A(p)$ and $X_A(2)$ exactly once, respectively, hence $f_2/\|f_2\|_2|_{X_A(p)}$ is a bijection. Moreover, it is easy to see that $X_A(p)$ is compact and $X_A(2)$ is

Hausdorff; since a closed subspace of a compact space is compact, and a compact subspace of a Hausdorff space is closed, it follows that $f_2/\|f_2\|_2|_{X_A(p)}$ is closed and hence a homeomorphism by the bijectiveness. As a conclusion, its inverse $f_p/\|f_p\|_p|_{X_A(2)}$ is continuous. \square

Theorem 3.5. *The continuous function*

$$\begin{aligned} \Phi_A(p): X_A(p) \times \mathbb{R}^d \times \mathbb{R}_{>0} &\longrightarrow \mathcal{S}_A \\ (z, T, r) &\longmapsto r(z_i e^{\langle A_i, T \rangle})_{i=1}^m \end{aligned}$$

is a homeomorphism, for all $p \geq 1$.

Proof. It suffices to find a continuous inverse for $\Phi_A(p)$. Suppose that $f_p(z)/\|f_p(z)\|_p = (x_i(z))_{i=1}^m$; for $(z, T, r) \in X_A(2) \times \mathbb{R}^d \times \mathbb{R}_{>0}$, we can rewrite

$$z = \rho^{-1}(z) F(f_p(z)/\|f_p(z)\|_p, T_2(f_p(z)/\|f_p(z)\|_p)) = \rho^{-1}(z) (x_i(z) e^{\langle A_i, T_2(f_p(z)/\|f_p(z)\|_p) \rangle})_{i=1}^m,$$

where $\rho(z) = \|(x_i(z) e^{\langle A_i, T_2(f_p(z)/\|f_p(z)\|_p) \rangle})_{i=1}^m\|_2$. The continuity of $\rho^{-1}(z)$, $x_i(z)$ and $e^{\langle A_i, T_2(f_p(z)/\|f_p(z)\|_p) \rangle}$ follows from Proposition 3.4 (by Theorem 1, T_2 is smooth). Observe that

$$\begin{aligned} \Phi_A(2)(z, T, r) &= r(z_i e^{\langle A_i, T \rangle})_{i=1}^m = r \rho^{-1}(z) (x_i(z) e^{\langle A_i, T + T_2(f_p(z)/\|f_p(z)\|_p) \rangle})_{i=1}^m \\ &= \Phi_A(p)(f_p(z)/\|f_p(z)\|_p, T + T_2(f_p(z)/\|f_p(z)\|_p), r \rho^{-1}(z)), \end{aligned}$$

hence we have a coordinate transition function

$$\begin{aligned} \varphi: X_A(2) \times \mathbb{R}^d \times \mathbb{R}_{>0} &\longrightarrow X_A(p) \times \mathbb{R}^d \times \mathbb{R}_{>0} \\ (z, T, r) &\longmapsto (f_p(z)/\|f_p(z)\|_p, T + T_2(f_p(z)/\|f_p(z)\|_p), r \rho^{-1}(z)). \end{aligned}$$

It is straightforward to check the continuity of φ , thus $\varphi \circ (\Phi_A(2))^{-1}$ is the inverse of $\Phi_A(p)$. \square

Corollary 3.6. *The function*

$$(12) \quad T_p: \mathcal{S}_A \rightarrow \mathbb{R}^d, \text{ s.t. } f_p(z) = F(z, T_p(z)),$$

is well defined and continuous. That is to say, for each $z \in \mathcal{S}_A$, $T_p(z)$ is the unique solution of the equation

$$\sum_{i=1}^m A_i |z|_i^p e^{p \langle A_i, T \rangle} = \mathbf{0},$$

which depends on z continuously.

4. WHEN p TENDS TO INFINITY

In this section we treat $T_p(z)$ and $f_p(z)$ that are defined in Corollary 3.6 and Proposition 3.2 respectively as functions of $p \in [1, \infty)$, with $z \in \mathcal{S}_A$ fixed.

Lemma 4.1. *There exists a bound $N(z)$, such that $\|T_p(z)\|_2 < N(z)$ for all $p \in [1, \infty)$.*

Proof. By definition, $\|F(z, T_p(z))\|_p$ is the unique minimum in the leaf L_z . Suppose that on the contrary, there exists a sequence $\{p_k\}_{k=1}^\infty$ tending to infinity, such that $\|T_{p_k}(z)\|_2 > k$, for all k . First by Lemma 3.3 and Cauchy-Schwarz inequality (10), $\|F(z, T)\|_1$ becomes arbitrary large whenever $\|T\|_2$ is large enough, thus

$$\exists N > 0, \text{ s.t. } \forall k > N, m\|F(z, T_1(z))\|_1 < \|F(z, T_{p_k}(z))\|_1.$$

Then by Hölder's inequality (11), we have

$$\sqrt[q_k]{m}\|F(z, T_1(z))\|_{p_k} \leq \sqrt[q_k]{m}\|F(z, T_1(z))\|_1 < \|F(z, T_{p_k}(z))\|_1 \leq \sqrt[q_k]{m}\|F(z, T_{p_k}(z))\|_{p_k}$$

where $1/p_k + 1/q_k = 1$, it follows that $\|F(z, T_{p_k}(z))\|_{p_k}$ is strictly greater than $\|F(z, T_1(z))\|_{p_k}$, yielding a contradiction. \square

Proposition 4.2. *$T_p(z)$ is continuous for all $p \in [1, \infty)$.*

Proof. Suppose again on the contrary, there is a sequence $\{p_k\}_{k=1}^\infty$ with $\lim_k p_k = p_0$, but $\|T_{p_k}(z) - T_{p_0}(z)\|_2 \geq \delta$, for some $\delta > 0$. Without loss of generality we may assume that $\lim_k T_{p_k} = T_0 \neq T_{p_0}(z)$, or we can choose a subsequence satisfying the property, by the lemma above. Consider the smooth function

$$\begin{aligned} \mu: [1, \infty) \times \mathbb{R}^d &\longrightarrow \mathbb{R}^d \\ (p, T) &\longmapsto \sum_{i=1}^m A_i |z_i|^p e^{p\langle A_i, T \rangle}, \end{aligned}$$

we have $\mathbf{0} = \lim_k \mu(p_k, T_k(z)) = \mu(p_0, T_0)$ by continuity, contradicting to the uniqueness (see Corollary 3.6). \square

Corollary 4.3. *As a function of $p \in [1, \infty)$, $f_p(z)/\|f_p(z)\|_p$ is continuous with its image in the L^p -link $X_A(p)$ (defined by (6)), and we have*

$$(13) \quad \lim_{p \rightarrow \infty} \|f_p(z)/\|f_p(z)\|_p\|_\infty = 1.$$

Proof. Denote $f_p(z)/\|f_p(z)\|_p$ by $y(p) = (y_i(p))_{i=1}^m$. Observe that

$$1 = \|y(p)\|_p = \|y(p)\|_\infty \left(\sum_{i=1}^m \left| \frac{y_i(p)}{\|y(p)\|_\infty} \right|^p \right)^{\frac{1}{p}},$$

where the last term in the bracket does not exceed m , thus (13) holds as desired. \square

4.1. Moment-angle complexes. Let K_A be the simplicial complex defined by (7). The associated moment-angle complex $(D^2, S^1)^{K_A}$ is defined as the polyhedral product

$$(14) \quad (D^2, S^1)^{K_A} = \bigcup_{\sigma \in K_A} D(\sigma); \quad D(\sigma) = \prod_{i=1}^m Y_i, \quad Y_i = \begin{cases} D^2 = \{|z| \leq 1 \mid z \in \mathbb{C}\} & \text{if } i \in \sigma, \\ S^1 = \{|z| = 1 \mid z \in \mathbb{C}\} & \text{otherwise.} \end{cases}$$

The proposition below implies that $f_p(z)/\|f_p(z)\|_p \in X_A(p)$ approaches $(D^2, S^1)^{K_A}$ as p tends to infinity.

Proposition 4.4. *Let S_∞ be the unit sphere of \mathbb{C}^m with respect to the L^∞ -norm, and let $z \in \mathcal{S}_A$ be a given point. Then for every point $z' = (z'_i)_{i=1}^m \in S_\infty \cap \mathcal{S}_A \setminus (D^2, S^1)^{K_A}$, $f_p(z)/\|f_p(z)\|_p$ will go outside of the set*

$$C(z') = \{(z_i)_{i=1}^m \in \mathbb{C}^m \mid |z_i| \leq |z'_i|, \forall i = 1, 2, \dots, m\},$$

whenever p is sufficiently large.

Proof. Denote by $B \subset \mathbb{R}^d$ the union of all convex hulls of the form $\text{conv}A([m] \setminus \tau)$ with $\tau \subset [m]$ not contained in K_A (in other words, $\mathbf{0} \notin \text{conv}A([m] \setminus \tau)$). It is clear that B is empty when and only when K_A bounds the $(m-1)$ -simplex (i.e. $K_A = 2^{[m]} \setminus [m]$, this happens only when $d = 0$, by the admissibility of A), which means $S_\infty = (D^2, S^1)^{K_A}$ and we have nothing to prove; otherwise B is compact thus there is an open neighborhood U_B such that $\mathbf{0} \notin U_B$.

Suppose the contrary, namely there is a sequence $\{p_k\}_{k=1}^\infty$ tending to infinity, such that $x_k = (x_{ki})_{i=1}^m = f_{p_k}(z)/\|f_{p_k}(z)\|_p \in C(z')$. Since $C(z')$ is compact, we may assume that $\{x_k\}_{k=1}^\infty$ converges to a point $x_0 = (x_{0i})_{i=1}^m \in C(z')$, without loss of generality.

We claim that the vector

$$(15) \quad \sum_{i=1}^m A_i |x_{ki}|^{p_k}$$

lies in U_B whenever k is large enough. Notice that this will be a contradiction since $x_k \in X_A(p)$, whose definition implies that the vector above should always be zero.

To see this, first note that because $x_0 \notin (D^2, S^1)^{K_A}$, there exists $\tau \notin K_A$, such that $|x_{0i}| < \delta < 1$ for all $i \in \tau$. This means for those $i \in \tau$, there exists an $N > 0$, such that $|x_{ki}| < \delta < 1$ holds when $k > N$; thus for any given $\varepsilon > 0$, we can find $N_\varepsilon > N$, such that $|x_{ki}|^{p_k} < \varepsilon$ for all $k > N_\varepsilon$. It is not difficult to see that, if ε is small enough, vector (15) shall lie in U_B , as claimed. \square

5. THE CONVERGENCE

In this section we shall prove that the function $f_p(z)/\|f_p(z)\|: \mathcal{S}_A \rightarrow X_A(p)$ indeed converges to a point in $(D^2, S^1)^{K_A}$, as one may expect from Proposition 4.4, with an additional assumption that A is centered at the origin (see (8)). The main technique we use here is combinatorial, in which Gale transforms play an essential role.¹

Suppose $V = (V_1, V_2, \dots, V_m)$ is a tuple of vectors in \mathbb{R}^{m-d-1} , such that the affine dimension of V is $m-d-1$, i.e. the matrix with columns $(V_i^T, 1)^T$ ($i = 1, 2, \dots, m$) has rank $m-d$.

Denote by $A_V = (A_1, A_2, \dots, A_m)$ the *Gale transform* of V (cf. [Grü03, Chapter 5.4, pp. 85–86]), which is the transpose of a basis of solutions of the following linear system

$$(16) \quad \begin{cases} \sum_{i=1}^m V_i x_i = 0, \\ \sum_{i=1}^m x_i = 0. \end{cases}$$

It is clear that each A_i is a vector in \mathbb{R}^d and different choices of A_V are linearly equivalent.

Recall that for any $J \subset [m]$, the subtuple $V(J) = (V_i)_{i \in J}$ is a *face* of V , if the intersection of $\text{conv}V([m] \setminus J)$ with the affine space spanned by vectors in $V(J)$ is empty (cf. [Grü03, Chapter 5.4, p. 88]). For instance, if V consists of the vertices of a convex polytope P , then $V(J)$ is a face of V when and only when $\text{conv}V(J)$ is a face of P . Now we need two facts about Gale transforms:

Proposition 5.1 (cf. [Grü03, Chapter 5.4, p. 88]). *Let $V = (V_i)_{i=1}^m$ be a tuple of vectors in \mathbb{R}^{m-d-1} , whose affine dimension is $m-d-1$, and let $A_V = (A_i)_{i=1}^m$ be its Gale transform.*

Then for any $I \subset [m]$, $\text{conv}V([m] \setminus I)$ is a face of V if and only if either I is empty or $\mathbf{0}$ is in the relative interior of $\text{conv}A_V(I)$.

Moreover, V coincides with the vertex set of a convex polytope P if and only if either

- (i) $d = 0$ (thus P is a simplex) or
- (ii) for every open halfspace H^+ of \mathbb{R}^d containing $\mathbf{0}$ in its closure, we have $\text{card}(\{i \mid A_i \in H^+\}) \geq 2$.

¹I would like to thank the referee for pointing out that analogues of Lemma 5.2 and Proposition 5.3 are already proven in [MV04] and [BM06], where Gale transforms have been intensely used. The approach here is motivated by those in these works.

It follows that if V is centered at the origin, then the double Gale transform of V gives the same configuration in \mathbb{R}^{m-d-1} . However, this is not true in general (see Remark 5.5).

Based on the facts above, we have the following lemma (in which we use the same notations with those in Proposition 5.1).

Lemma 5.2. *Suppose that every vector of V is a face, and every face of V has at most $m - d - 1$ vectors. Then V coincides with the vertex set of a convex polytope P , whose boundary is simplicial.*

Proof. Let $A_V = (A_i)_{i=1}^m$ be the Gale transform of V . It suffices to show either (i) or (ii) in Proposition 5.1 holds. Note that the case $d = 0$ is trivial: this happens if and only if V spans an $(m - 1)$ -simplex in \mathbb{R}^{m-1} .

Now suppose that $d > 0$. Notice that by Proposition 5.1, the Siegel and weak hyperbolicity conditions hold for A_V , with the assumption above. Moreover, since every vector in V is a face, we have $\mathbf{0} \in \text{conv} A_V(J)$, for all J with $\text{card}(J) = m - 1$.

Let H^+ be an open halfspace of \mathbb{R}^d with $\mathbf{0}$ on the boundary. From its admissibility, A_V has rank d , with a neighborhood of $\mathbf{0} \in \mathbb{R}^d$ contained in $\text{conv} A_V$ (see Lemma 3.1), hence there exists $A_i \in A_V$, such that $A_i \in H^+$. Observe that now $\mathbf{0} \in \text{conv} A_V([m] \setminus \{i\})$ with $A_V([m] \setminus \{i\})$ again admissible, by the same argument, there exists another $A_j \in A_V$ with $A_j \in H^+$, which means (ii) holds hence the statement follows. \square

Proposition 5.3. *Let K_A be the simplicial complex induced from an admissible m -tuple $A = (A_i)_{i=1}^m$ centered at the origin, with vectors in \mathbb{R}^d . Let the tuple $V = (V_i)_{i=1}^m$ be the transpose of a basis of the system*

$$(17) \quad \begin{cases} \sum_{i=1}^m A_i x_i = \mathbf{0}, \\ \sum_{i=1}^m x_i = 0, \end{cases}$$

then $\{V_i\}_{i \in K_A}$ is the vertex set of a convex polytope P_A of affine dimension $m - d - 1$, with each V_j in its interior, where $\{j\} \notin K_A$. Moreover, the boundary of P_A is isomorphic to K_A and we can assume that P_A contains $\mathbf{0}$ in its interior.

Proof. First from Lemma 3.1, the affine dimension of V is $m - d - 1$.

Since the centroid of A is $\mathbf{0}$, now A is the Gale transform of V , with the subtuple $(V_i)_{i \in K_A}$ satisfying the assumptions in Lemma 5.2, thus it coincides with the vertex set of a convex polytope P_A , whose boundary is simplicial. For those $\{j\} \notin K_A$, if V_j lies outside, or on the boundary of P_A , it must be in a

face of V that is contained in a supporting hyperplane of P_A ; by Proposition 5.1, this is impossible.

The last statement is also a consequence of Proposition 5.1, together with the observation that any translation of the form $V + v_0 = (V_i + v_0)_{i=1}^m$ also satisfies (17). \square

Example 5.4. Let A be the 5-tuple given by the matrix

$$\begin{pmatrix} 0 & 0 & 1 & 1 & -2 \\ 1 & 1/2 & 0 & 0 & -3/2 \end{pmatrix}$$

which is admissible and centered at the origin. By solving (17) we can choose V that is given by

$$\begin{pmatrix} 0 & 0 & -1 & 1 & 0 \\ 6 & -9 & 2 & 0 & 1 \end{pmatrix}.$$

Observe that the last point $(0, 1)^T$ is in the interior of the square spanned by the other four vertices.

Remark 5.5. Note that Proposition 5.3 is independent of the choice of V . If the centroid of A is not at the origin, Proposition 5.3 may not hold. Consider the case that A is given by the matrix (one can check its admissibility)

$$\begin{pmatrix} 1 & 1 & 4 & -2 \\ 4 & -2 & 1 & 1 \end{pmatrix},$$

then we choose $V = (-1, -1, 1, 1)$ by (17), but now points $V_2 = (-1)$ and $V_4 = (1)$ are not contained in the interior of $P_A = \text{conv}(V_1, V_3)$. This is because the Gale transform of V can be

$$\begin{pmatrix} 0 & 0 & 1 & -1 \\ 1 & -1 & 0 & 0 \end{pmatrix},$$

which is no longer admissible.

The following proposition is essentially due to Panov and Ustinovsky (cf. [PU12]).

Proposition 5.6. *Let $A = (A_i)_{i=1}^m$ be an admissible m -tuple centered at the origin. Then for each $z \in \mathcal{S}_A$ given, there is a unique pair $(r, T) \in \mathbb{R}_{>0} \times \mathbb{R}^d$ such that $\Phi_A(z, T, r) = r(z e^{\langle A_i, T \rangle})_{i=1}^m \in (D^2, S^1)^{K_A}$ (see (14) for definition).*

Proof. The proof presented here is adapted from [Pan13, Theorem 9.2, pp. 37–40]. Observe that in the trivial case when $d = 0$, i.e. K_A is a simplex, we can simply take $r = \|z\|_\infty^{-1}$. In what follows suppose $d > 0$.

Let $\mathbb{R}_{\geq 0}$ (resp. $\mathbb{R}_{\leq 0}$) be the set of non-negative (resp. non-positive) real numbers. Note that it suffices to prove the cases when $z \in (\mathbb{R}_{\geq 0})^m$, since for each

$z = (z_i)_{i=1}^m \in \mathbb{C}^m$, there is a rotation $e^{\sqrt{-1}\theta} = (e^{\sqrt{-1}\theta_i})_{i=1}^m \in (S^1)^m$, such that $e^{\sqrt{-1}\theta} z = (e^{\sqrt{-1}\theta_i} z_i)_{i=1}^m \in (\mathbb{R}_{\geq 0})^m$, and we have

$$e^{\sqrt{-1}\theta} \Phi_A(z, T, r) = \Phi_A(e^{\sqrt{-1}\theta} z, T, r).$$

For the tuple $A = (A_i)_{i=1}^m$, let $V = (V_i)_{i=1}^m$ be the tuple defined in Proposition 5.3, which satisfies (17). Since A is centered at the origin, the row vectors of $\tilde{V} = (\tilde{V}_i)_{i=1}^m$ with $\tilde{V}_i = (V_i^T, 1)^T$ is a basis of the orthogonal complement of the space spanned by the row vectors of A .

Let α be the linear morphism

$$\begin{aligned} \alpha: \mathbb{R}^m &\longrightarrow \mathbb{R}^{m-d} \\ (x_i)_{i=1}^m &\longmapsto \sum_{i=1}^m \tilde{V}_i x_i. \end{aligned}$$

For $x = (x_i)_{i=1}^m \in (\mathbb{R}_{\geq 0})^m$, we shall abbreviate $(\ln(x_i))_{i=1}^m$ as $\ln(x)$ in what follows.

First we consider the case $z \in \mathcal{S}_A \cap (\mathbb{R}_{>0})^m$. Observe that there exists a pair $(r, T) \in \mathbb{R}_{>0} \times \mathbb{R}^d$ such that $y = (y_i)_{i=1}^m = \Phi_A(z, T, r)$ when and only when $\ln(y) - w - \ln(z) = (\langle A_i, T \rangle)_{i=1}^m$, where $w = (w_i)_{i=1}^m$ with $w_i \equiv \ln(r)$, and this happens if and only if the vector $\ln(y) - w - \ln(z)$ belongs to $\text{Ker}(\alpha)$.

Let $(\mathbb{R}_{\leq 0}, 0)^{K_A}$ be the following polyhedral product

$$(18) \quad (\mathbb{R}_{\leq 0}, 0)^{K_A} = \bigcup_{\sigma \in K_A} D(\sigma); \quad D(\sigma) = \prod_{i=1}^m Y_i, \quad Y_i = \begin{cases} \mathbb{R}_{\leq 0} & \text{if } i \in \sigma, \\ \{0\} & \text{otherwise,} \end{cases}$$

and it is clear that $y \in (D^2, S^1)^{K_A} \cap (\mathbb{R}_{>0})^m$ if and only if $\ln(y) \in (\mathbb{R}_{\leq 0}, 0)^{K_A}$, hence now it suffices to find a unique pair $(u, c) \in ((\mathbb{R}_{\leq 0}, 0)^{K_A}, \mathbb{R})$, such that

$$(19) \quad \sum_{i=1}^m (V_i^T, 1)^T (u_i + c) = \sum_{i=1}^m (V_i^T, 1)^T \ln(z_i)$$

holds, where $u = (u_i)_{i=1}^m$. Let \overline{P}_A be the convex polytope spanned by $\{-V_i\}_{i \in K_A}$.

By Proposition 5.3, \overline{P}_A contains a neighborhood of $\mathbf{0}$ in its interior, and the boundary of \overline{P}_A is the union $-\bigcup_{\sigma \in K_A} \text{conv} V(\sigma)$, which is simplicially isomorphic to K_A . Therefore every vector ν in \mathbb{R}^{m-d-1} has a unique expression $\rho \nu_0$, where $\rho \in \mathbb{R}_{\geq 0}$ and ν_0 lies in the relative interior of the corresponding face. Together with the observation $\sum_{i=1}^m V_i = \mathbf{0}$ (see (17)), we conclude that there exists a pair $(u, c) \in ((\mathbb{R}_{\leq 0}, 0)^{K_A}, \mathbb{R})$ such that

$$\sum_{i=1}^m V_i u_i = \sum_{\{i\} \in K_A} V_i u_i = \sum_{i=1}^m V_i \ln(z_i), \quad \sum_{i=1}^m (\ln(z_i) - u_i) = \sum_{i=1}^m c = mc,$$

namely (19) holds, which is unique by the construction.

Next we consider general cases when $z \in \mathcal{S}_A \cap \mathbb{R}_{\geq 0}^m$ with $\bar{I}_z = \{i \mid z_i = 0\}$ not empty. First note that by definition, \bar{I}_z is a simplex of K_A . Let $\pi_z: \mathbb{R}^{m-d-1} \rightarrow \mathbb{R}^{m-d-1-\text{card}(\bar{I}_z)}$ be the orthogonal projection onto the linear subspace

$$\bigcap_{i \in \bar{I}_z} \{\nu \in \mathbb{R}^{m-d-1} \mid \langle \nu, V_i \rangle = 0\},$$

and denote by $\text{Link}(\bar{I}_z, K_A)$ the union

$$\{\sigma \in K_A \mid (\sigma \cup \bar{I}_z) \in K_A, \sigma \cap \bar{I}_z = \emptyset\},$$

which is a subcomplex of $\text{Star}(\bar{I}_z, K_A) = \{\sigma \in K_A \mid \bar{I}_z \subset \sigma\}$. It is not difficult to see that in the image of π_z , $\pi_z(\text{conv}V(\text{Star}(\bar{I}_z, K_A)))$ is a convex polytope bounded by $\pi_z(\text{conv}V(\text{Link}(\bar{I}_z, K_A)))$ (for example, by induction on $\text{card}(\bar{I}_z)$). Then by a similar argument as in the previous case, we deduce that there exists a unique $u = (u_i)_{i=1}^m$ in the polyhedral product $(\mathbb{R}_{\leq 0}, 0)^{\text{Link}(\bar{I}_z, K_A)}$ (defined by replacing K_A with $\text{Link}(\bar{I}_z, K_A)$ in (18)), such that

$$\pi_z\left(\sum_{i=1}^m V_i u_i\right) = \pi_z\left(\sum_{i=1}^m V_i \chi(z_i) \ln(z_i)\right); \quad \chi(z_i) \ln(z_i) = \begin{cases} \ln(z_i) & \text{if } |z_i| > 0, \\ 0 & \text{otherwise;} \end{cases}$$

note that vectors of $\{V_i\}_{i \in \bar{I}_z}$ are linearly independent, hence we have a unique $x = (x_i)_{i=1}^m \in \mathbb{R}^m$ with $I_x \subset \bar{I}_z$, such that

$$\sum_{i=1}^m V_i(u_i + x_i) = \sum_{i=1}^m V_i \chi(z_i) \ln(z_i)$$

holds. With c obtained from

$$\sum_{i=1}^m (\chi(z_i) \ln(z_i) - u_i - x_i) = mc,$$

we have

$$\sum_{i=1}^m (V_i^T, 1)^T (u_i + x_i + c) = \sum_{i=1}^m (V_i^T, 1)^T \chi(z_i) \ln(z_i).$$

At last, by solving $T \in \mathbb{R}^d$ from

$$\langle A_i, T \rangle = \chi(z_i) \ln(z_i) - u_i - x_i - c$$

for $i = 1, 2, \dots, m$, and setting $r = e^c$, we have $\Phi_A(z, T, r) \in (D^2, S^1)^{K_A}$ as desired; the uniqueness follows from the arguments above and the observation that the rank of A is d . \square

From Proposition 5.6, we can define a map $f_\infty: \mathcal{S}_A \rightarrow \mathcal{S}_A$, with $f_\infty(z)$ the point in the leaf L_z such that $f_\infty(z)/\|f_\infty(z)\|_\infty \in (D^2, S^1)^{K_A}$.

The proofs of the following Proposition 5.7 and Theorem 5.8 are similar to the ones for Proposition 3.4 and Theorem 3.5, respectively, which we shall omit here.

Proposition 5.7. *With the assumption that A is admissible and centered at the origin, the restriction $f_2/\|f_2\|_2|_{(D^2, S^1)^{K_A}}: (D^2, S^1)^{K_A} \rightarrow X_A(2)$ is a homeomorphism, whose inverse is the restriction $f_\infty/\|f_\infty\|_\infty|_{X_A(2)}: X_A(2) \rightarrow (D^2, S^1)^{K_A}$.*

Theorem 5.8. *The continuous function*

$$\begin{aligned} \Phi_A(\infty): (D^2, S^1)^{K_A} \times \mathbb{R}^d \times \mathbb{R}_{>0} &\longrightarrow \mathcal{S}_A \\ (z, T, r) &\longmapsto r(z_i e^{\langle A_i, T \rangle})_{i=1}^m \end{aligned}$$

is a homeomorphism, provided that A is admissible and centered at the origin.

Recall that for each $p \in [1, \infty)$, we have defined $T_p: \mathcal{S}_A \rightarrow \mathbb{R}^d$ such that $f_p(z) = F(z, T_p(z))$ has the minimal L^p -norm in each leaf F_z . By Theorem 3.5, T_p is the composition of $\Phi_A^{-1}(p)$ and the projection onto \mathbb{R}^d , and $f_p(z)/\|f_p(z)\|_p$ is the composition of $\Phi_A^{-1}(p)$ and the projection onto $X_A(p)$.

Corollary 5.9. *Let $T_\infty: \mathcal{S}_A \rightarrow \mathbb{R}^d$ be the composition of $\Phi_A^{-1}(\infty)$ and the projection onto \mathbb{R}^d , with A admissible and centered at the origin. Then we have*

$$\lim_{p \rightarrow \infty} T_p(z) = T_\infty(z),$$

which means

$$\lim_{p \rightarrow \infty} f_p(z)/\|f_p(z)\|_p = f_\infty(z)/\|f_\infty(z)\|_\infty,$$

with any $z \in \mathcal{S}_A$ given.

Proof. By Lemma 4.1, Corollary 4.3 and Proposition 4.4, there exists a sequence $\{p_k\}_{k=1}^\infty$ such that $\{T_{p_k}(z)\}_{k=1}^\infty$ converges to a point $T_0 \in \mathbb{R}^d$, and $\{f_{p_k}(z)\}_{k=1}^\infty$ converges to some y_0 such that $y_0/\|y_0\|_\infty \in (D^2, S^1)^{K_A}$. We claim that

$$\lim_{p \rightarrow \infty} T_p(z) = T_0 = T_\infty(z)$$

with

$$\lim_{p \rightarrow \infty} f_p(z)/\|f_p(z)\|_p = y_0/\|y_0\|_\infty = f_\infty(z)/\|f_\infty(z)\|_\infty.$$

Note that

$$y_0/\|y_0\|_\infty = \lim_{k \rightarrow \infty} \Phi_A(z, T_k(z), \|f_{p_k}\|_{p_k}^{-1}) = \Phi_A(z, T_0, \|y_0\|_\infty^{-1}) \in (D^2, S^1)^{K_A}$$

which is uniquely determined by z (see Proposition 5.6), therefore $y_0/\|y_0\|_\infty$ must be $f_\infty(z)/\|f_\infty(z)\|_\infty$ and T_0 must be $T_\infty(z)$. It is not difficult to see that the argument above is independent of the choice of the sequence $\{p_k\}_{k=1}^\infty$, hence the claim holds and the proof is completed. \square

6. SOME APPLICATIONS

In this section we shall revisit several known results from another perspective. First notice that by Proposition 5.3, a simplicial complex K_A induced from an admissible tuple that is centered at the origin can be realized as the boundary of a convex polytope dual to a simple one; the converse is also true: for a convex polytope with simplicial boundary, the Gale transform of its vertices will be a tuple with the property above.

Our first application is an alternative proof of a rigidity theorem on polytopal moment-angle manifolds, due to Bosio and Meersseman:

Proposition 6.1 (cf. [BM06, Theorem 4.1]). *Let K_A and $K_{A'}$ be the simplicial complexes induced from two admissible m -tuples A and A' that are centered at the origin, respectively. If there is a simplicial isomorphism $\phi: K_A \rightarrow K_{A'}$, then there is a diffeomorphism between $X_A(2)$ and $X_{A'}(2)$.*

Proof. Observe that under the assumption, ϕ can be extended as a bijection from $[m]$ to itself (possibly not unique), and let $\tilde{\phi}: \mathcal{S}_A \rightarrow \mathcal{S}_{A'}$ be the diffeomorphism via permuting coordinates with respect to ϕ . Clearly $\tilde{\phi}$ gives a homeomorphism between associated moment-angle complexes $(D^2, S^1)^{K_A}$ and $(D^2, S^1)^{K_{A'}}$. On the other hand, we have a smooth map $(f'_2/\|f'_2\|_2) \circ \tilde{\phi}: X_A(2) \rightarrow X_{A'}(2)$ given in the diagram

$$\begin{array}{ccc}
 \mathcal{S}_A & \xrightarrow[\text{diffeo.}]{\tilde{\phi}} & \mathcal{S}_{A'} \\
 \uparrow & & \downarrow f'_2/\|f'_2\|_2 \\
 X_A(2) & \xrightarrow{(f'_2/\|f'_2\|_2) \circ \tilde{\phi}} & X_{A'}(2) \\
 \downarrow f_\infty/\|f_\infty\|_\infty \text{ homeo.} & & \uparrow f'_2/\|f'_2\|_2 \text{ homeo.} \\
 (D^2, S^1)^{K_A} & \xrightarrow[\text{homeo.}]{\tilde{\phi}} & (D^2, S^1)^{K_{A'}},
 \end{array}$$

where $f'_2: \mathcal{S}_{A'} \rightarrow \mathcal{S}_{A'}$ is the function of L^2 -norm minima of Siegel leaves. By the commutativity, it follows that $(f'_2/\|f'_2\|_2) \circ \tilde{\phi}$ is a homeomorphism (see Theorem 1 and Proposition 5.7), whose inverse can be constructed by interchanging the roles of A and A' , which is also smooth. \square

In what follows we shall discuss everything with \mathbb{C}^m replaced by its subspace \mathbb{R}^m . In the foliation \mathcal{F} given by the action (1), a leaf L_z lies in $\mathcal{S}_A \cap \mathbb{R}^m$ if and only if $z \in \mathcal{S}_A \cap \mathbb{R}^m$. Therefore all properties hold true when restricted to the real case.

We will still use the same notations as in the previous sections, with the exception that the notation $(D^1, S^0)^{K_A}$ is used for the associated *real moment-angle complex*, i.e., the intersection of $(D^2, S^1)^{K_A}$ with \mathbb{R}^m (see (14) for details).

Notice that the real version of Proposition 6.1 holds, namely the \mathbb{Z}_2^m -equivariant (where \mathbb{Z}_2^m acts on $X_A(2)$ by changing the signs of coordinates) smooth structures on $X_A(2)$ are determined by combinatorial types of K_A . This can be deduced from a result of Wiemeler in [Wie13, Corollary 5.2] (see also [Dav13, Corollary 1.3]).

Recall that a subspace X of \mathbb{R}^m is a *polyhedron*, if for every point $x \in X$ there is a compact set C_x , such that $x * C_x = \{ax + bl \mid l \in C_x, a + b = 1, a, b \geq 0\}$ is a neighborhood of x in X . For instance, $(D^1, S^0)^{K_A}$ and $X_A(1)$ are polyhedra embedded in \mathbb{R}^m , hence they can be triangulated (cf. e.g. [RS72, Theorem 2.11]).

A polyhedron X is a piecewise linear (abbr. PL) n -manifold if given certain triangulation, the link of each vertex is PL homeomorphic to the boundary of an n -simplex or to an $(n - 1)$ -simplex (i.e. these homeomorphisms become simplicial after suitable subdivisions on both sides). Note that this property is independent of the triangulation chosen for X (cf. e.g. [RS72, pp. 20–22]).

Definition 6.2 (Whitehead triangulation). Let X be a polyhedron and M a smooth manifold. A map $\eta: X \rightarrow M$ is a *piecewise differentiable* (abbr. PD) homeomorphism if there exists a triangulation of X , such that the restriction of η to each simplex is smooth with the Jacobian matrix non-degenerate. Such a PD homeomorphism η is called a *Whitehead triangulation* of M , and also a *smoothing* of X .

Note that by Propositions 3.4 and 5.7, the smooth function $f_2/\|f_2\|_2: \mathcal{S}_A \rightarrow X_A(2)$ induces a homeomorphism when restricted to either $(D^1, S^0)^{K_A}$ or $X_A(1)$. Moreover, the following lemma holds:

Lemma 6.3. *Let $A = (A_i)_{i=1}^m$ be an admissible tuple centered at the origin. If a space $Y \subset \mathbb{R}^m$ is either*

- (a) *the intersection of the L^p -link $X_A(p)$ (defined by (6)) with the first orthant of \mathbb{R}^m (i.e. points with non-negative coordinates), for any $p \geq 1$, or*
- (b) *a component of the polyhedral product $D(\sigma) = (D^1, S^0)^\sigma$ (see (14) for definition, with the pair replaced), for any $\sigma \in K_A$ with maximal dimension,*

then Y is a smooth manifold with corners, and the differential of $f_2/\|f_2\|_2$ at any point of Y induces a linear injection between corresponding tangent spaces.

Proof. First we show that each Y is indeed a smooth manifold with corners, in both cases. For (b) this is obvious since Y is a cube of dimension $m - d - 1$. As for (a), observe that for each $\sigma \in K_A$ with $\text{card}(\sigma) = k$, the augmented subtuple $\tilde{A}([m] \setminus \sigma)$ has rank $d + 1$, where $\tilde{A} = (\tilde{A}_i)_{i=1}^m$ with $\tilde{A}_i = (A_i^T, 1)^T$ (see Lemma 3.1), therefore the row vectors of \tilde{A} , together with canonical basis vectors $e_i \in \mathbb{R}^m$ (the vector with only i -th coordinate non-zero, which is one) for all $i \in \sigma$, form a matrix of rank $d + k + 1$. This means that the intersection

$$Y \bigcap_{i \in \sigma} F_i$$

is transverse, where $F_i = \{(x_i)_{i=1}^m \in \mathbb{R}^m \mid x_i = 0\}$.

Recall that $\Phi_A(2): X_A(2) \times \mathbb{R}^d \times \mathbb{R}_{>0} \rightarrow \mathcal{S}_A$ is a diffeomorphism, such that $f_2/\|f_2\|_2 \circ \Phi_A(2)$ is the identity on $X_A(2)$ (see Theorem 1). Let

$$d\Phi_A(2)_x: \mathbb{R}^{m-d-1} \times \mathbb{R}^d \times \mathbb{R} \rightarrow \mathbb{R}^m \in T_{\Phi_A(2)(x)}\mathcal{S}_A,$$

be the differential of $\Phi_A(2)$ at the point x , and let ζ be the linear subspace $\{\mathbf{0}\} \times \mathbb{R}^d \times \mathbb{R} \subset \mathbb{R}^m$ of dimension $d + 1$. It suffices to show that for all $y = (y_i)_{i=1}^m \in Y$ with $x = (x_i)_{i=1}^m = f_2(y)/\|f_2(y)\|_2$, the intersection of the image of $d\Phi_A(2)_x|_\zeta$ with the tangent space $T_y Y$ is trivial.

For (a), note that from its definition (6), the tangent space $T_y Y$ is the orthogonal complement of the $(d + 1)$ -space spanned by the row vectors of the $((d + 1) \times m)$ -matrix

$$\tilde{A}_{y^{p-1}} = ((A_i^T, 1)^T y_i^{p-1})_{i=1}^m$$

and the image of $d\Phi_A(2)_x|_\zeta$ is spanned by the row vectors of $\tilde{A}_y = ((A_i^T, 1)^T y_i)_{i=1}^m$. From the previous argument, the subtuple $\tilde{A}_{y^{p-1}}(I_y)$ has rank $d + 1$ ($I_y \subset [m]$ is the set of non-zero entries of y), hence any row vector of $\tilde{A}_y(I_y)$ cannot be orthogonal to the corresponding one in $\tilde{A}_{y^{p-1}}(I_y)$, otherwise itself must be zero (since we can write each y_i^p as a square).

As for (b), the tangent space at $y \in (D^1, S^0)^\sigma$ is spanned by $\{e_i \mid i \in \sigma\}$, where $\text{card}(\sigma) = m - d - 1$. But we have shown that the row vectors of $\tilde{A}_y(I_y)$ and the basis of $T_y Y$ has a full rank m , therefore the intersection of the image of $d\Phi_A(2)_x|_\zeta$ with $T_y Y$ must be trivial. \square

As a corollary, we find that with given triangulations, the restriction of $f_2/\|f_2\|_2$ to either $(D^1, S^0)^{K_A}$ or $X_A(1)$ will be a Whitehead triangulation of $X_A(2)$. By a theorem of Whitehead (cf. [Whi40]), if there is a PD homeomorphism from a polyhedron X to a smooth manifold M , then X is a PL manifold, and the PL structure on X is uniquely determined by the smooth structure given on

M . Consequently, it follows that $(D^1, S^0)^{K_A}$ and $X_A(1)$ are homeomorphic as PL manifolds.

At last, we make a conclusion to end this section.

Proposition 6.4. *For each simplicial complex K_A induced from an admissible m -tuple A centered at the origin, there is a PD homeomorphism from $(D^1, S^0)^{K_A}$ onto the smooth manifold $X_A(2)$, thus $(D^1, S^0)^{K_A}$ is a PL manifold of dimension $m - d - 1$. If $(D^1, S^0)^{K_A}$ has an exotic PL structure, then either it is not smoothable, or $X_A(2)$ must have different smooth structures.*
